

Guild rulebook

What you control, what it costs and how your output becomes a Titan.

The shared mission

All six guilds build one supply chain. In five rounds, ship at least 3 Titans (very easy), 7 (moderate) or 9 (very hard). Only Titans approved by Inspection count. Every guild must keep at least 1 gold, including after final settlement. Default: 10 gold per guild.

Six guilds, six jobs

Guild / turn	Input -> output
1. Frames	Raw material -> frames
2. Engines	Raw material -> engines
3. Armour	Raw material -> armour
4. Subassembly	1 frame + 1 engine -> 1 subassembly
5. Final assembly	1 subassembly + 1 armour -> 1 Titan to inspect
6. Inspection	Inspect final Titans; only approved Titans count

How output is calculated

Each guild has 8 hours per round; a normal unit needs 4 hours. Repairs and scheduled work use those hours. Available capacity is 0, 1 or 2 units, never more than 2. Actual output cannot exceed complete input sets. Example: capacity 2, frames 2 and engines 1 -> only 1 subassembly. Leftover stock carries forward. Inspection has the extra rework rule below.

Your turn: four simple steps

CHECK. Select your guild in the role menu. Wait for your name on the action panel. Look at input stock, gold, work hours and the Titan target.

PREDICT. Enter expected output (0, 1 or 2), external charges for this round and machine-incident risk (%). Write a short reason, then click "Lock prediction". The game checks routine risk automatically.

RESPOND. Follow only the action shown. Roll only when asked. Choose a remedy if needed. Before release, consider a technician or negotiate support in "Recovery agreements".

RELEASE & LEARN. Ask the Game Master to click "Release good units". Compare actual output with your prediction in the ledger. Explain the difference; do not reroll or rewrite the prediction.

Supply: three votes before delivery

At the start of each round, Frames, Engines and Armour each vote; at least two votes choose the contract for all three. Standard: no assurance premium; 30% supplier-incident risk. Assured: 1 gold from EACH component guild (3 total); 10% risk. Each needs at least 2 gold to pay and survive. The computer resolves delivery automatically. Normally each receives 2 new raw units. A delay delivers 1 now and 1 next round; a quality incident places a defect in one incoming raw batch. Delayed units from earlier rounds arrive in addition to new receipts. Supplier risk never changes machine risk.

Routine machine risk is automatic

For an eligible turn without prevention: 10% major fault, 10% minor fault, 80% no fault. A turn already at zero for a known reason skips this check. Active verified prevention cancels a fault from the matching cause; it does not replace it with another fault.

Guild rulebook / reference

Follow the displayed action. Keep at least 1 gold after every payment.

When a fault appears: choose, do not guess

Choice	Gold cost	What happens
Temporary repair	Minor: 1; major: 2	Pay now. Use 4h (minor) or 8h (major) this round. No future protection.
Diagnosis	1	Reveals the cause only. Does not repair or restore hours. Then choose another remedy.
Corrective action	Minor: 2-3; major: 3-4	Pay repair cost + 1 prevention premium + 1 diagnosis if the cause is unknown. Use the same 4h/8h. Then verify with D6.
Hold / defer repair	0 now; 1 or 2 later	Zero output this turn. Schedule 4h/8h for next round and pay then. An unpaid final-round invoice is collected at settlement.

D6 checks future prevention, not today's output

After corrective action, roll D6 once. 2-6: prevent the matching cause for the next three rounds. 1: no future prevention; the current repair still takes place. Prevention does not stack and does not protect against other causes. A successful diagnostic D10 already identifies the cause, so that action needs no extra diagnosis charge.

Dice: let the game tell you

No production D6 and no supplier D10. If your initial feasible output is 1 or 2, skip D10. Known zero output (missing inputs, scheduled work or a known quality restriction) also skips D10. Only a new unexplained zero-output stoppage gets ONE free D10: 1-5 inconclusive; 6-10 identifies the existing cause. No reroll, extra cost or new fault. Physical D10: 0 means 10. A later repair may restore output without another D10.

One technician for the whole factory

Before release, buy the technician for 2 gold when the button is available: recover up to 4 eligible work hours. There is only ONE service slot per round across all six guilds. It cannot create materials, exceed 2 units, cancel a hold or remove Inspection's extra rework time. Compare output with and without the service before paying.

Support another guild with a clear promise

In "Recovery agreements", a sponsor offers 2 gold to the active guild for a technician, plus a quantity (1 or 2 units), deadline and reason. Acceptance transfers the gold and buys the service together. The sponsor must retain 1 gold. The promise measures the recipient's TOTAL new output after acceptance, not the extra output caused by support. It is best-efforts: the game records met/missed; there is no automatic penalty or repayment. Unaccepted offers expire when that guild releases.

Inspection: good first, suspect units wait

Inspection chooses "Rework" or "Hold" when locking its prediction. Clean Titans need 4h each and are processed first. A defective Titan needs 8h in total (4h normal + 4h rework), plus 1 gold; Inspection must have at least 2 gold before rework. Without enough time or gold, it stays in final stock. QA "Hold" keeps defective units only; clean units may still ship. No defective Titan ships. Rework is paid by Inspection, not automatically by the recorded defect source.

Never spend your last gold

Any guild reaching 0 or less stops the whole factory. Arrange support BEFORE a payment or next-round invoice exhausts its gold. A normal transfer just moves gold; it does not repair, buy stock or create output. The sender must retain at least 1 gold. Recorded gold charges are selected extra costs, not sales, profit or full production costs.

Guild rulebook / reference

Dice and production: use the rules for the version you are playing.

What is one unit?

One unit means one frame, engine, armour component, subassembly, assembled Titan or approved Titan, depending on the guild. A frame is not a shipped Titan. Only Inspection-approved Titans count towards the mission. In version 4.1, output is calculated from available hours and complete input sets; it is NOT assigned by a production D6.

Production: 0, 1 or 2 units

0 units = no complete output is released by this guild. A required input may be missing, fewer than 4 usable hours may remain, a repair may occupy the day, or a hold may block release. Example: 2 frames + 0 engines = 0 subassemblies, even with 8 hours. A known shortage does not trigger D10; only a new unexplained zero-output stoppage does.

1 unit = one complete output unit is released, not a half-finished unit. An ordinary production stage may have 4-7 usable hours and at least one input set, or time for two units but inputs for only one. Example: 2 frames + 1 engine and 8 hours give 1 subassembly; the unused frame remains in stock.

2 units = two complete outputs: full normal daily capacity. An ordinary stage needs 8 usable hours, two complete input sets and no hold. Example: 2 frames + 2 engines and 8 hours give 2 subassemblies. Extra materials alone cannot raise the limit above 2.

Inspection exception: a clean Titan needs 4 hours. A defective Titan needs 8 hours including rework, plus 1 gold, and Inspection must retain 1 gold. Thus 8 hours can approve two clean Titans OR one defective Titan after rework. QA Hold keeps defective Titans waiting but does not stop clean Titans from shipping. Displayed output is the final release after these checks.

D6: what every result means in version 4.1

D6 means a six-sided die numbered 1-6. Roll ONCE only when verification is requested after corrective action. There is no production D6 in version 4.1 and no face 0. A verification result is not a count of units produced.

Roll 1: no future prevention is established. The current repair still takes place; its charge and work hours remain. This does NOT automatically mean zero production today.

Roll 2, 3, 4, 5 or 6: verification succeeds. Prevent the matching fault cause for the next three rounds. Other causes remain possible; protection does not stack. Output still depends on hours, inputs and quality release.

Example: a minor corrective repair uses 4 of the 8 hours. With enough inputs and no other constraint, output can be 1 unit whether D6 is 1 or 5. The difference is future prevention, not today's unit count. Successful verification does not restore all 8 hours.

Guild rulebook / reference

Dice and production: use the rules for the version you are playing.

D10: what every result means in version 4.1

D10 is a ten-sided diagnostic die. The game requests ONE free roll for a new unexplained stoppage with initial feasible output 0. It is not a production or supplier-risk die. Do not roll for output 1 or 2, missing inputs, scheduled work or a known quality restriction.

Roll 1, 2, 3, 4 or 5: inconclusive diagnosis. The existing cause remains unknown; the roll adds no new fault, cost or downtime. No reroll. Choose a remedy; paid diagnosis is available, and corrective action includes a diagnosis charge if the cause is still unknown.

Roll 6, 7, 8, 9 or 10: the existing cause is identified. All five faces mean successful diagnosis, NOT five different faults. Identification alone does not repair the fault or add output. Corrective action now needs no extra diagnosis charge for that cause.

Physical D10 marked 0-9: 0 means 10, not zero production. The 4.1 input form accepts 0 and records it as 10. Example: D10 = 8 after an unexplained zero identifies the cause, but a remedy must still be chosen. D10 = 3 leaves it unknown without another roll.

D4: an older-edition die, not a version 4.1 action

D4 is a four-sided die numbered 1-4. Version 4.1 does NOT use it: choose Temporary repair, Diagnosis, Corrective action or Hold/defer repair on screen. In the older 15-round edition ONLY: 1 = Stop and investigate (4h / 1 gold); 2 = Root cause analysis (8h / 2 gold); 3 = Software / parts fix (0h / 0 gold); 4 = Rework (8h / 2 gold charged to the origin). In that older system, 1 and 3 apply only to failure or misalignment, 4 only to defective parts, and 2 to any non-vendor incident. Inapplicable results are rerolled there, not in 4.1. No D4 face represents a production quantity.
